ACCEPTED

11 Abstract

12 In this study, we analyzed the physicochemical and sensory properties of black goat jerky  
13 marinated with various spices (non-spice, CO; rosemary, RO; basil, BA; ginger, GI; turmeric,  
14 TU; and garlic, GA). The physicochemical properties of black goat jerky analyzed were pH,  
15 water holding capacity, color, cooking yield, shear force, and fatty acid composition. The  
16 sensory characteristics were analyzed through the aroma profile (electronic nose), taste profile  
17 (electronic tongue), and sensory evaluation. The pH and water holding capacity of the GI  
18 showed higher values than the other samples. GI and GA showed similar values of lightness  
19 and redness to that of the control CO. The shear force of the GI and TU was significantly  
20 lower than that of other samples ( $p < 0.05$ ). Regarding fatty acid composition, GI showed  
21 high unsaturated and low saturated fatty acid contents compared with that of the other  
22 samples except for RO ( $p < 0.05$ ). In the aroma profile, the peak area of hexanal, which is  
23 responsible for a faintly rancid odor, was lower in all treatment groups than in the control. In  
24 the taste profile, the umami of spice samples was higher than that of the control, and among  
25 the samples, GI had the highest score. In the sensory evaluation, the GI sample showed  
26 significantly higher scores than the control in terms of flavor, aroma, goaty flavor, and overall  
27 acceptability ( $p < 0.05$ ). Therefore, marinating black goat jerky with ginger powder enhanced  
28 the overall flavor and reduced the goat odor.

29 Keywords: black goat, jerky, spice, goaty flavor, volatile compounds, fatty acid  
30 composition

31

## 32 Introduction

33 In the recent meat market, there has been an increase in the number of consumers seeking  
34 high-quality meat products with nutritionally superior functions (Manzoor et al., 2022). Goat  
35 meat, known for its high protein, trace element, and low-fat contents, is a healthier option  
36 than other red meat types (Kawęcka et al., 2022). Furthermore, the absence of religious  
37 restrictions, such as those for pork or beef, has contributed to the global rise in goat meat  
38 consumption (Qi et al., 2022). The global production of goat meat has grown significantly,  
39 increasing from approximately 5.6 million tons in 2015 to approximately 6.2 million tons in  
40 2019, displaying an overall increase of approximately 0.6 million tons in four years (Popescu  
41 et al., 2021). Accordingly, in order to maximize the consumption of goat meat, the  
42 development of new meat products using goat meat is in progress (Teixeira et al., 2020).

43 Smoking, drying, and curing are among the oldest methods used for meat preservation, and  
44 jerkies are a processed meat product with a long history (Cheng et al., 2023). Moreover, it is a  
45 globally high-demand snack food as a ready-to-eat meat product that can be stored at room  
46 temperature (Gaikwad et al., 2020). There are two main types of jerkies: whole muscle jerkies  
47 produced by curing and drying thin slices of whole muscle and restructured jerkies made by  
48 grinding raw meat, followed by curing, molding, and drying (Lemma et al., 2022). The drying  
49 process in jerkies extends the meat storage period by controlling water activity and inhibiting  
50 microbial growth (Kim et al., 2021). Moreover, the hydrolysis and oxidation of fat during  
51 drying are responsible for the distinctive flavor development in jerkies (Han et al., 2020).

52 Flavor, a sensory attribute of food detected through taste and smell, is an important factor  
53 influencing consumers' decision to purchase meat (Khan et al., 2015). The flavor of cooked  
54 meat arises from aromatic volatile organic compounds (VOCs) and non-VOCs generated  
55 through heat in the matrix of muscle fibers, connective tissues, and fat depots (Sgarro et al.,  
56 2022). However, depending on the type of livestock animal and the storage and cooking

57 methods after slaughter, an off-flavor instead of the desired flavor may occur (Gómez et al.,  
58 2020). The unique goaty flavor can influence consumer preference, and various processing  
59 techniques, such as spice addition, thermal processing, and irradiation, are required to  
60 enhance preference (Jia et al., 2021; Jia et al., 2022; Qi et al., 2022). Spices are natural  
61 additives derived from extracting or drying the seeds, flowers, roots, or leaves of various  
62 plants (Ağaoğlu et al., 2007). Spices impart a unique taste and aroma based on their main  
63 ingredients and are usually added in small amounts to food, effectively reducing off-flavors  
64 and enhancing overall flavors (Sachan et al., 2018).

65 The primary objective of this study is to investigate methods for reducing the goaty flavor  
66 by analyzing the physicochemical and sensory characteristics of black goat jerky based on  
67 different spice treatments (rosemary, basil, ginger, turmeric, and garlic) commonly used to  
68 remove food odors.

## 69 70 Materials and Methods

### 71 Prepared to black goat meat and various spice powder

72 The raw meat used for jerky production was purchased from Gaon (Gang-jin, Republic of  
73 Korea). It was sourced from the front and hind whole legs of black goats (Boer × black  
74 Korean goat; female; 12 months old), obtained 24 hours after slaughter. Before use, excess  
75 connective tissues were removed from the meat. The powders in this study were purchased  
76 online in 100% form without additives. These included ginger, turmeric, and garlic powders  
77 (Gomine, Gyeonggi-do, Republic of Korea), basil powder (Sun-jae Food, Gyeonggi-do,  
78 Republic of Korea), and rosemary powder (Garunara, Seoul, Republic of Korea). The pH and  
79 color characteristics of each spice were as follows: rosemary (pH: 5.73; L\*: 61.35, a\*: 4.29,  
80 b\*: 22.54), basil (pH: 5.98; L\*: 55.34, a\*: 3.70, b\*: 18.39), ginger (pH: 7.43; L\*: 70.70, a\*:  
81 8.20, b\*: 28.90), turmeric (pH: 6.55; L\*: 55.48, a\*: 19.49, b\*: 35.38), and garlic (pH: 6.21;

82 L\*: 81.33, a\*: 8.25, b\*: 24.68). A curing agent was prepared by mixing 1.5% salt, 1.5% sugar,  
83 and 0.2% spice based on 100% meat (Table 1).

84

#### 85 Preparation of black goat jerky

86 Jerkies were produced using the methods outlined in Kim et al. (2008) with certain  
87 modifications. The front and hind leg meat of black goats were sliced to a thickness of 7–8  
88 mm in the same direction as the muscle fibers. Random sampling of the meat slices was  
89 performed to minimize deviations in different muscle parts. The sliced raw meat was evenly  
90 coated with the curing agent without spice or with 0.2% rosemary, basil, ginger, turmeric, or  
91 garlic, followed by 1 min of hand massaging. After applying the curing agent, the cured black  
92 goat meats were vacuum-packed and stored (cured) for 18 h at 4°C. After curing, the black  
93 goat meat was cooked and dried in a chamber (10.10ESI/sk, Alto Shaam, Menomonee Falls,  
94 WI, USA) using the following temperature method: 90 min at 72°C, 60 min at 65°C, and 60  
95 min at 55°C. The final jerkies were obtained after 1 h of cooling at 20°C (room temperature).

96 The samples before cooking were utilized to measure the pH, water holding capacity  
97 (WHC), and color, while those after cooking were used to measure the cooking yield, shear  
98 force, and fatty acid composition and to perform electronic nose and electronic tongue  
99 analyses and sensory evaluations.

100 At this time, the moisture content and water activity ( $a_w$ ) of the cooked black goat jerky are  
101 as follows: control (CO; non-spice; moisture contents - 35.58%;  $a_w$  - 0.72), black goat jerky  
102 marinated with rosemary (RO; moisture contents - 37.69%;  $a_w$  - 0.74), black goat jerky  
103 marinated with basil (BA; moisture contents - 39.69%;  $a_w$  - 0.75), black goat jerky marinated  
104 with ginger (GI; moisture contents - 31.96%;  $a_w$  - 0.71), black goat jerky marinated with  
105 turmeric (TU; moisture contents - 34.90%;  $a_w$  - 0.73), black goat jerky marinated with garlic  
106 (GA; moisture contents - 30.25%;  $a_w$  - 0.69).

107 pH

108 To measure the pH of samples, 3 g of the sample was added to 12 mL of distilled water,  
109 and the solution was homogenized for 1 min at 10,000 rpm using an ultraturrax (HMZ-20DN,  
110 Poonglim Tech, Seongnam, Korea). Homogeneous samples were measured using a glass  
111 electrode pH meter (Model S220, Mettler-Toledo, Schwerzenbach, Switzerland). The pH  
112 meter was calibrated with pH 4.01, pH 7.00, and pH 10.00 buffer solutions (Suntex  
113 Instruments Co, Ltd, Taipei, Taiwan).

114

115 Color

116 The color was measured using a colorimeter (CR-10, Minolta, Tokyo, Japan) equipped  
117 with a pulsed xenon lamp, 2° standard observer, aperture of 8 mm, and illuminant D65. The  
118 lightness (CIE L\*), redness (CIE a\*), and yellowness (CIE b\*) of the sample surface were  
119 recorded; the spice on the sample surface was not removed, and the samples bloomed at 25°C  
120 for 30 min, then the color was measured. The device was calibrated using a white standard  
121 plate (CLE L: +97.83, CIE a: -0.43, CIE b: -1.98).

122

123 Water-holding capacity (WHC)

124 The WHC of the black Korean goat jerky sample was measured using the filter paper press  
125 method (Go et al., 2023). First, 0.3 g of the sample inner part was placed in the center of the  
126 filter paper (Whatman No. 1, GE Healthcare, Chicago, IL, USA) and compressed for 3 min at  
127 a constant pressure using a Plexiglass plate device. The pressed sample surface and the  
128 exudation areas were measured using a Digitizing Area-lines Sensor (MT-10S, MT Precision,  
129 Tokyo, Japan). WHC was calculated as a percentage by substituting the following formula:

130

$$WHC (\%) = \frac{Meat\ area\ (mm^2)}{Exudation\ area\ (mm^2)} \times 100$$

131

## 132 Cooking yield

133 The cooking conditions were the same as the jerky manufacturing conditions. The cooking  
134 yield was determined by measuring the weight of the sample before and after cooking.  
135 Subsequently, the measured value was calculated as a percentage by substituting the  
136 following formula.

$$137 \quad \text{Cooking yield (\%)} = \frac{\text{Sample weight after cooking (g)}}{\text{Sample weight before cooking (g)}} \times 100$$

138

## 139 Shear force

140 The shear force was measured using a Texture Analyzer (TA1, Lloyd, Largo, FL, USA)  
141 with a V-blade attached. The black goat jerky (1.0 × 3.0 × 0.3 cm; length × width × height),  
142 which had been molded parallel to the muscle fiber direction, was cut perpendicular to the  
143 muscle fiber direction. Then, the analysis conditions were as follows: a test speed of 2 mm/s,  
144 distance of 22 mm, force of 5.6 N, and the measured values were expressed in Newtons (N).

145

## 146 Fatty acid composition

147 For fatty acid composition, lipids were extracted using the method previously described by  
148 Folch et al. (1957). The sample and chloroform-methanol (2:1) were mixed and homogenized  
149 for 1 min at 10,000 rpm with a homogenizer (AM-5, Nihonseiki Kaisha Ltd., Tokyo, Japan).  
150 Subsequently, 0.88% KCl was added and centrifuged for 10 min at 3000 rpm using a  
151 centrifuge (Supra R22, Hanil Science, Gimpo, Korea) at 2°C. The supernatant was removed,  
152 and the lower layer was filtered using a filter paper (Whatman No. 1, GE Healthcare, Chicago,  
153 IL, USA). Then, it was concentrated using an N<sub>2</sub> gas blow concentrator (MGS-2200, Eyla  
154 Tokyo Rikakikai Co., Tokyo, Japan) at 38°C. The concentrated lipids were methylated with  
155 0.5 N NaOH (in methanol) and 14% boron trifluoride (in methanol) according to the method

156 previously described by David et al. (2002). Subsequently, 5 mL of distilled water and 2 mL  
157 of hexane were mixed and centrifuged for 10 min at 2°C and 3000 rpm. Then, 1 µL was  
158 injected into a gas chromatography equipped with an HP-Innowax column (100 m length ×  
159 0.32 mm id × 0.25 µm film thickness, Agilent Technologies, Inc. Palo Alto, CA, USA) for  
160 analysis. The analysis conditions were inlet temperature: 225°C, split ratio: 1/10, carrier: heat  
161 1 mL/min, oven program: 150°C for 1 min, 150–200°C at 15/min, 200–250°C at 2/min,  
162 250°C for 10 min; FID temperature: 280°C. Each fatty acid peak analyzed was calculated as a  
163 percentage (%) of the total fatty acid peak area after comparison and identification with the  
164 retention time of the standard material (47015-U, PUFA No. 2 Animal Source, Supelco,  
165 Bellefonte, PA, USA).

#### 166 167 Electronic nose (E-nose)

168 E-nose was used by referring to the method of Xie et al. (2023). Each cooked sample was  
169 homogenized, and 5 g was weighed into a 20 mL headspace vial. The analyses were  
170 performed using an electronic nose system (Heracles-II-e-nose, Alpha MOS, Toulouse,  
171 France) under the conditions of injection speed 125 µL/s, injection temperature 200°C, trap  
172 absorption temperature 80°C, trap desorption temperature 250°C, and acquisition time 110 s.  
173 The MXT-5 and MXT-1701 columns were used. Classified data were reported as primary  
174 component values (PC1) and secondary component values (PC2).

#### 175 176 Electronic tongue (E-tongue)

177 E- tongue was used by referring to the method of Zhu et al. (2022). E-tongue analysis was  
178 performed using a taste sensor E-tongue (Astree V, Alpha MOS, Toulouse, France). First, 4 g  
179 of black goat jerky sample was homogenized for 1 min at 10,000 rpm using 16 mL of distilled  
180 water and a homogenizer (AM-5, Nihonseiki Kaisha Ltd., Tokyo, Japan). The homogenized

181 sample was filtered using the Whatman No.1 filter paper (Whatman No. 1, GE Healthcare,  
182 Chicago, IL, USA). Then, the filtrate was diluted 1000-fold in distilled water and measured  
183 using a taste sensor E-tongue. The analysis measured the signal intensity at each sensor using  
184 taste sensors: NMS (umami), AHS (sourness), and CTS (saltiness), along with auxiliary  
185 sensors SCS and CPS, and standard sensors PKS and ANS.

186

#### 187 Sensory evaluation

188 The sensory evaluation was performed with approval from the Kongju University  
189 Institutional Bioethics Committee (Authorization Number: KNU\_IRB\_2021-75). Samples  
190 were prepared by cutting them into blocks of 1.0 cm × 1.0 cm and then distributed randomly  
191 for evaluation. The sensory panelists (15 people) conducted the evaluation and were  
192 sufficiently educated on samples and evaluation criteria. Based on the control jerky, spice-  
193 added jerky was evaluated. The mouth was rinsed with water every time the treatment was  
194 changed. The color, flavor, texture, aroma, and overall acceptability of the cooked black goat  
195 jerky samples were evaluated on a scale of 10, with 10 being the “best” and 1 being the  
196 “worst” score. In the case of goaty flavor, the treatment group with less goat odor received a  
197 higher score in the evaluation.

198

#### 199 Statistical analysis

200 For all data in this study, at least three experiments were repeated to obtain the results,  
201 expressed as mean ± standard deviation. To minimize the deviation across the raw meat  
202 samples used in the experiments, pre-curing samples of black goat meat were randomized for  
203 the experiments. One-way analysis of variance (ANOVA) was performed on the results  
204 obtained through the procedures of the generalized linear model (GLM). Tukey’s studentized

205 range test was used to test the significance at  $p < 0.05$ . All statistical analyses were performed  
206 using the SAS software (Version 9.3 for Windows, SAS Institute Inc., Cary, NC, USA).

## 207 Results and Discussion

### 208 pH and color

209 pH is a critical factor affecting the taste and overall quality of meat (Ribeiro et al., 2021).  
210 Table 2 presents the pH and color of cured black goat meat according to the treatment with  
211 various spice marinades. The GI and RO exhibited the highest and lowest pH, respectively,  
212 with significance ( $p < 0.05$ ). The pH of the ginger and rosemary powders used in this study  
213 were 7.43 and 5.73, respectively, and it was judged that the pH of the powder affected the pH  
214 of the jerky. Vişan et al. (2021) reported that the pH of Black Angus sirloin was influenced by  
215 the composition of the spice the meat was marinated with, consistent with the findings of this  
216 study. The pH of the meat is negatively correlated with drip loss and may affect the quality  
217 characteristics of meat products, such as color, flavor, and shelf-life (Vergara et al., 2020; Xu  
218 et al., 2020). Therefore, various spice treatments of jerkies could impact qualities such as  
219 WHC and cooking yield.

220 In this study, the cured black goat meats were experimented without rinsing off the curing  
221 agent, and it is presumed that the unique color of the spice remaining on the surface had an  
222 impact on the color of the jerkies. The TU showed significantly higher lightness than the other  
223 spice treatment groups for the raw black goat jerkies ( $p < 0.05$ ). The RO and BA exhibited  
224 lower lightness than the other treatment groups. It is known that meat marinades containing  
225 green-colored additives can reduce the lightness of meat before cooking (Kim et al., 2019).  
226 The GI and GA showed similar lightness to the control, which agrees with Cózar et al. (2018)  
227 and Singh et al. (2014), reporting that marinades containing yellow-colored additives have  
228 little impact on meat lightness. Regarding redness, the control, GI, and GA did not vary  
229 significantly, whereas the RO, BA, and TU exhibited significantly lower redness than the

230 other treatment groups ( $p < 0.05$ ). As green and red are complementary colors, green-colored  
231 additives reduce the meat products' redness (Lim et al., 2013). Hence, the green-colored  
232 rosemary ( $a^*$ : 4.29) and basil ( $a^*$ : 3.70) powders with low redness likely reduced the redness  
233 of the marinated meat. In the case of yellowness, the TU displayed a significantly higher  
234 value than other treatment groups ( $p < 0.05$ ), and the BA showed the lowest value. Turmeric  
235 contains a large amount of curcumin, which is yellowish-orange (Duda et al., 2020). The  
236 yellowness of basil powder was the lowest among the various powders used in this study, at  
237 approximately 18.39, leading to the low yellowness of the BA. The color analysis of black  
238 goat jerkies revealed that the GI and GA had the most similar color to the control. Thus, the  
239 treatment with garlic powder has been determined not to affect the color of the product in the  
240 manufacture of black goat jerkies.

241

242 Water-holding capacity (WHC), cooking yield, and shear force

243 Table 3 presents the WHC, cooking yield, and shear force of cured black goat meat  
244 /cooked black goat jerkies according to the treatment with various spice marinades. The GI  
245 showed the highest WHC. This shows a similar result to the pH of black goat jerky and is  
246 consistent with the results of Ali et al. (2021), which reported that an increase in anions in  
247 muscle fibers produces electrostatic repulsions to expand muscle fibers and improve the  
248 WHC. The improved WHC increases the heat transfer efficiency in muscles, and as the heat is  
249 evenly transferred to the whole muscle upon cooking while maintaining a high surface  
250 temperature on the muscles, numerous products of the Maillard reaction can be obtained with  
251 consequent generation of flavor/ The improved WHC increases the heat transfer efficiency in  
252 muscles, and when heated, heat is not only evenly transferred to the whole muscle but also a  
253 large amount of Maillard reaction products that cause flavor can be generated by maintaining  
254 the surface temperature of the muscle high. (Kerth and Miller, 2015). However, the RO

255 showed the lowest WHC. Sun et al. (2018) reported that a fall in pH could reduce WHC and  
256 cause the denaturation of certain muscle proteins. Thus, the low WHC of the RO is likely to  
257 reduce the quality of black goat jerkies.

258 Cooking yield is an important production indicator of the economic values of meat (Zhang  
259 et al., 2023). An increase in WHC results in an increase in immobilized water bound to the  
260 proteins in muscles, thereby increasing the cooking yield (Yang et al., 2022). Although the  
261 cooking yield displayed a similar trend to the WHC, no significant variation was found across  
262 the spice treatment groups ( $p > 0.05$ ).

263 The shear force of black goat jerkies was the lowest in the GI compared with that of all  
264 other treatment groups. The water content of meat products increases as the WHC of meat  
265 increases, and the increased moisture leads to softer and tender meat tissues, thus reducing the  
266 shear force (Hughes et al., 2014). However, the RO showed significantly higher shear force  
267 than all the other treatment groups except the BA ( $p < 0.05$ ). Kim et al. (2020a) reported that  
268 WHC and shear force were negatively correlated in aged Korean beef, consistent with the  
269 finding of this study. The low WHC is also presumed to have caused the high shear force of  
270 the RO and BA in this study. Yang et al. (2009) performed a sensory evaluation of pork  
271 jerkies according to the drying temperature and time and reported that the shear force at 70–  
272 80 N indicated the maximum hardness of jerkies that consumers could accept. In this study,  
273 the GI and TU showed 75.16 N and 77.43 N of shear force, respectively, which is predicted to  
274 offer a favorable texture to consumers.

275

#### 276 Fatty acid composition

277 Fatty acids are involved in producing various VOCs, and the fatty acid composition is a  
278 key factor in the final sensory quality of meat and meat products (Ba et al., 2019). Table 4  
279 presents the fatty acid composition of black goat jerkies according to the treatment with

280 various spice marinades. This study revealed varying fatty acid compositions based on the  
281 type of spices used in the preparation of black goat jerky. The main fatty acids in black goat  
282 jerkies were palmitic acid (C16:0), stearic acid (C18:0), and oleic acid (C18:1n9), in  
283 agreement with Lee et al. (2017), reporting the same compounds as the main fatty acids in  
284 black goat jerkies. Spices possess their own fatty acid compositions, and when incorporated  
285 into meat processing, they influence the fatty acid composition of the resulting product  
286 (Muzolf-Panek and Kaczmarek, 2021). Unsaturated fatty acids (UFAs) and polyunsaturated  
287 fatty acids (PUFAs) contents were significantly higher in the RO and GI than in the other  
288 treatment groups ( $p < 0.05$ ). Xia et al. (2021) reported that various aroma and flavor  
289 compounds, including aldehydes, ketones, alcohols, esters, and aliphatic series, were  
290 produced via the oxidation of UFAs. Various hydroperoxides were produced to form flavor  
291 compounds as PUFAs, such as linoleic acid, arachidonic acid, and eicosapentaenoic acid,  
292 were degraded (Al-Dalali et al., 2022). Additionally, Dinh et al. (2021) reported that UFAs  
293 undergo the oxidation reaction more readily than saturated fatty acids (SFAs) as they have at  
294 least one double bond in their structure, facilitating the conversion into flavor compounds.  
295 Hence, the RO and GI enriched with UFAs led to an abundance of flavor compounds  
296 compared with that by the other treatment groups, positively affecting the sensory properties  
297 of jerkies. The GA and BA showed significantly higher contents of SFAs than the other  
298 treatment groups ( $p < 0.05$ ). SFAs are generally known to have a negative impact on VOCs in  
299 meat and meat products (Morrill et al., 2017). Analyzing the fatty acid composition revealed  
300 that spice marinades influenced the fatty acid composition of black goat jerkies, while the RO  
301 and GI were effective in enhancing flavor and reducing the goaty flavor of black goat jerkies.  
302  
303 E-nose

304 The results of principal component analysis and VOCs of black goat jerkies using the E-  
305 nose and the treatment with various spice marinades are shown in Fig. 1 and Table 5. The  
306 dispersion of PC1 (X-axis) and PC2 (Y-axis) was 74.165% and 21.093%, respectively, with  
307 the data differentiated mainly according to the differences in PC1 across samples (Fig. 1). The  
308 control group was located on the rightmost area on the X-axis, and to the left of the control  
309 group were the RO, TU, BA, GA, and GI in the order of proximity, confirming clear  
310 distinction of black goat jerkies with different spice marinades. While the RO was found in a  
311 positive direction on the Y-axis, the control, BA, GI, TU, and GA were found in a negative  
312 direction. It is conjectured that a specific compound in rosemary distinguished the Y-axis.

313 Black goat jerkies are classified based on the spice and seven expected goat-related VOCs  
314 in Table 5. The VOC with the highest value in the control and spice treatment groups was  
315 deduced to be ethanol, with the GI exhibiting the highest value of ethanol. As one of the  
316 VOCs abundantly detected in meat, ethanol adds an alcoholic, pungent, and sweet aroma and  
317 flavor (Kim et al., 2020b). Aldehydes contribute significantly to the aroma profile of meat due  
318 to their low threshold of odor and specific aroma (Zhang et al., 2020). Among the aldehydes,  
319 hexanal displayed the highest peak area in the control compared with the treatment groups.  
320 Hexanal is a product of lipid oxidation associated with an unpleasant odor, acting as the main  
321 odor compound of goat meat (Jia et al., 2023). Ivanović et al. (2020) reported that a high  
322 hexanal concentration in mung beans could induce an unsavory and rotting smell. In this  
323 study, the intensity of hexanal expression was low in the RO, BA, and GI, indicating that the  
324 treatment with rosemary, basil, or ginger reduced the goaty flavor in black goat jerkies. In  
325 addition, 3-methylbutanoic acid is a carboxylic acid whose level was high in the RO and  
326 control. Moreover, 3-methylbutanoic acid is responsible for rancid, cheesy, and animal smells  
327 as it is derived from leucine in the Maillard reaction via the activities of rumen  
328 microorganisms (Pisinov et al., 2021). The content of 3-methylbutanoic acid, which

329 potentially contributes to the goaty flavor, was low in the GI and TU, indicating that the  
330 treatment with ginger and turmeric reduced the goaty flavor. Depending on the spice used in  
331 marinating black goat jerkies, the level of reduction of goaty flavor varied, and overall, the GI  
332 was more effective in reducing goaty flavor than other treatment groups.

333

334 E-tongue

335 The results of E-tongue analysis of black goat jerkies according to the treatment with  
336 various spice marinades are presented in Fig. 2. Umami is detected in the presence of  
337 compounds such as monosodium glutamate, inosine monophosphate, and guanosine  
338 monophosphate and is distinguishable by human senses (Wang et al., 2020). The GI showed  
339 the highest score of umami at 8.5, whereas the lowest score at 3.2 was found in the control.  
340 Umami positively affects food acceptability and enhances meat flavor by inhibiting bitterness  
341 (Zhu et al., 2022). Sourness was low in the control compared with the spice treatment groups,  
342 with the highest score of sourness found in the GI. Sourness can increase in meat products  
343 with increased ethanol content (Xu et al., 2021). Hence, the GI with the highest peak area of  
344 ethanol at 16199.42 in the E-nose analysis is presumed to have scored the highest in sourness.  
345 In contrast, saltiness was the lowest at 3.2 in the GI and the highest at 9.2 in the control. This  
346 decrease in saltiness is presumed to be due to the gingerol compound in ginger inhibiting the  
347 saltiness receptor epithelial sodium channel (Alipour et al., 2022; Vinitha et al., 2022). The E-  
348 tongue analysis confirmed that the spice treatment groups had a higher level of umami than  
349 the control. The GI, in particular, inhibited saltiness and was more effective in enhancing  
350 umami than the other treatment groups.

351

352 Sensory evaluation

353 Table 6 presents the sensory evaluation results of the treatment with various spice  
354 marinades. The flavor is a highly complex sensation that humans can detect. Flavor  
355 perception involves the interactions across olfactory and taste senses that detect the basic taste  
356 and aroma (Liu et al., 2022). The lowest flavor score was found in the control compared with  
357 the spice treatment groups, and the GI exhibited a significantly higher score than the control  
358 ( $p < 0.05$ ). Hexanal was shown to be responsible for the goaty flavor in the E-nose analysis,  
359 and its level was the highest in the control. Among the spice treatment groups, the BA, RO,  
360 and GI exhibited low scores. This finding implies that the differences in the contents of off-  
361 flavor compounds across the control and spice treatment groups had an impact on the sensory  
362 evaluation. Additionally, the fatty acid composition of the GI had high contents of UFAs and  
363 low contents of SFAs, which affected the flavor score. Regarding the aroma, the lowest score  
364 was found in the control compared with the spice treatment groups, while the GI and GA  
365 exhibited significantly higher scores than the control ( $p < 0.05$ ). Baker et al. (2013) and Javed  
366 et al. (2011) reported that, in the manufacture of meat products, the meat taste and flavor were  
367 enhanced by adding ginger and garlic, in agreement with the results of this study. Regarding  
368 goaty flavor and overall acceptability, the lowest scores were found in the control compared  
369 with the spice treatment groups, and the GI exhibited the highest scores. Singh et al. (2014)  
370 analyzed the odor scores of chicken meat emulsions according to the storage period and  
371 reported that high scores were found in the groups treated with ginger paste compared with  
372 those treated with garlic paste. Ultimately, as the GI exhibited higher scores of flavor, aroma,  
373 goaty flavor, and overall acceptability than the control, RO, BA, and TU, the treatment with  
374 ginger powder in the production of black goat jerkies is anticipated to have positive effects on  
375 enhancing flavor and reducing the goaty flavor.

376

377 Conclusion

378 This study investigated the use of rosemary, basil, ginger, turmeric, and garlic powders in  
379 curing black goat jerkies, and the resulting physicochemical and sensory properties were  
380 analyzed. The E-nose analysis revealed that the intensity of hexanal expression, which affects  
381 the goaty flavor, was low with rosemary, basil, and ginger powders, and the 3-methylbutanoic  
382 acid content, which induces the goaty flavor, was low in meat treated with ginger or turmeric  
383 powder. In the E-tongue analysis, ginger powder increased the sourness and umami of black  
384 goat jerkies but decreased the saltiness. In the sensory evaluation, ginger powder improved  
385 the flavor, aroma, goaty flavor, and overall acceptability of black goat jerkies. As a result of  
386 the study, it was confirmed that various spices reduce the goaty flavor of black goat, and  
387 enhance the overall flavor and umami. Among them, ginger powder showed the most  
388 outstanding effect. Thus, applying ginger to produce black goat jerkies is predicted to  
389 improve the quality and sensory properties.
